Abstract

We present a composite model of quarks with ‘effective supersymmetry’. The model is based on the gauge group $(SU(2)_S \times SU(2)_M) \times (SU(2)_U \times SU(2)_C \times SU(2)_T) \times SU(5)_{SM}$, where $SU(5)_{SM}$ is the standard model gauge group. In the dynamical supersymmetry breaking sector based on the gauge group $SU(2)_S \times SU(2)_M$, supersymmetry is dynamically broken. The preon sector is constructed by the model proposed by Nelson and Strassler. The fermion mass hierarchy among the up-type quarks originates from the $SU(2)_U \times SU(2)_C \times SU(2)_T$ gauge dynamics. The supersymmetry breaking is mediated to the minimal supersymmetric standard model sector by the ‘preon’ superfields which compose the quarks in the first two generations. To obtain an experimentally acceptable mass spectrum, the scalar quarks in the first two generations need masses of order 10 TeV, while the other superpartners need masses less than 1 TeV. Therefore, the mass spectrum in our model is one example of the ‘effective supersymmetry’ model proposed by Cohen, Kaplan and Nelson.

I. INTRODUCTION

The standard model gives no understanding of the origins of the electroweak symmetry breaking and the fermion mass hierarchy. Furthermore, it is well known that there exists a naturalness problem [1] in the standard model. The electroweak scale cannot be stable with respect to quantum corrections if new physics exists at very large scales.

The naturalness problem is solved by minimal supersymmetric (SUSY) extension of the standard model, the minimal supersymmetric standard model (MSSM). Although the extension gives no explanation of the origin of the fermion mass hierarchy, a new mechanism to break the electroweak symmetry is included. In this model, if SUSY is broken, the electroweak symmetry breaking is caused by the radiative correction due to the large top Yukawa coupling. This mechanism is known as the ‘radiative breaking scenario’ [2]. However, the supersymmetric mass term of the Higgs superfields, the μ -term, should be roughly less than the electroweak scale, so that this mechanism can work. Since the μ -term is a free parameter, its scale is not determined by the MSSM itself. This is known as the μ problem.

To understand the MSSM more completely, we should investigate three subjects as follows: (i) the mechanism of the SUSY breaking, (ii) a solution to the μ problem, (iii) an explanation of the large top Yukawa coupling and the fermion mass hierarchy.

The method proposed by Seiberg and co-workers [3] is noteworthy, when we consider the dynamical scale generation and the dynamical SUSY breaking in the $N = 1$ SUSY gauge theory. By this method, we can evaluate the non-perturbative effect of the strong gauge interaction and ‘exactly’ determine the dynamically generated superpotential. For example, there are many models [3-6] in which the SUSY is broken by the strong gauge dynamics.

On the other hand, the SUSY composite model proposed by Nelson and Strassler [7] is useful in understanding the large top Yukawa coupling and the fermion mass hierarchy among the up-type quarks. They introduce the $SU(2)$ gauge interaction with six doublet superfields, the ‘preon’ superfields. The MSSM gauge group $SU(5)_{SM} \supset SU(3)_c \times SU(2)_L \times U(1)_Y$ is embedded in the $SU(6)$ global symmetry. Below the dynamical scale of the $SU(2)$ gauge

interaction, the preon superfields are confined into the superfields of **5** and **10** representations of $SU(5)_{SM}$, which are identified with the up-type Higgs and the ten dimensional superfields in the conventional SUSY $SU(5)$ GUT framework. The top Yukawa coupling is dynamically generated by the non-perturbative effect of the $SU(2)$ gauge interaction, and is naturally expected to be $\mathcal{O}(1)$. In addition, the μ -term is also generated by strong dynamics. Unless the composite scale is much larger than the electroweak scale, the μ -term naturally becomes the electroweak scale. In the three generation case, three $SU(2)$ gauge interactions are introduced at each generation. Then, the Yukawa couplings of the up-type quarks are generated by each type of $SU(2)$ gauge dynamics. The small Yukawa couplings of the up and charm quarks are effectively generated through the mixing of the up-type Higgs superfields. The mass hierarchy among the up-type quarks can be understood as the hierarchy among the three composite scales.

An attempt to combine the SUSY composite model with the dynamical SUSY breaking model has been made in Ref. [8]. In this model, SUSY is dynamically broken, the large top Yukawa coupling is dynamically generated, and the radiative breaking scenario is realized. In addition, a new mechanism to give soft SUSY-breaking masses to the superpartners in the MSSM was proposed. Here, the preon superfield plays the role of the ‘messenger fields’ [4].

However, the model cannot satisfy the naturalness criterion [1], which is the motivation of the SUSY extension. In the model, the scalar top quark should have mass of order 10 TeV to give an experimentally acceptable mass spectrum in the MSSM. Then, fine tuning is necessary to obtain the correct vacuum expectation values of the Higgs bosons. In addition, since the composite scale is of order 10^9 GeV, an extremely small coupling constant is needed to obtain the μ -term of the electroweak scale.

In this paper, we present a composite model of quarks with ‘effective supersymmetry’. The model is based on the gauge group $(SU(2)_S \times SU(2)_M) \times (SU(2)_U \times SU(2)_C \times SU(2)_T) \times SU(5)_{SM}$. The dynamical SUSY breaking sector is based on the gauge group $SU(2)_S \times SU(2)_M$. The strong $SU(2)_S \times SU(2)_M$ interaction dynamically breaks SUSY

and generates the $U(1)_R$ symmetry-breaking mass term in the superpotential. The preon sector is constructed by the model proposed by Nelson and Strassler, and is based on the gauge group $SU(2)_U \times SU(2)_C \times SU(2)_T$. The quarks in the i -th generation are composed by the preon superfields which are confined by the strong $SU(2)_i$ gauge interaction, where $i = U, C$ and T correspond to the first, second and third generation, respectively. Since the gauge group $SU(2)_U \times SU(2)_C$ is embedded in the global symmetry of the dynamical SUSY breaking sector, the preon superfields in the first two generations play the role of the messenger fields. To obtain an experimentally acceptable mass spectrum in the MSSM, the scalar quarks in the first two generations need masses of order 10 TeV. On the other hand, the other superpartners need masses less than 1 TeV. Therefore, the mass spectrum in our model is one example of ‘effective supersymmetry’ model proposed by Cohen, Kaplan and Nelson [9].

In section II, we construct the preon sector which is based on the model proposed by Nelson and Strassler. In section III, the dynamical SUSY breaking sector is constructed. In section IV, we discuss the mediation of the SUSY breaking to low energy, and we estimate the mass spectrum in the MSSM. In section V, we show that the electroweak symmetry breaking is realized with an experimentally acceptable mass spectrum in the MSSM. In section VI, we consider the masses of the down-type quarks. We summarize our model in section VII.

II. THE PREON SECTOR

In this section we construct the preon sector, which is based on the model proposed by Nelson and Strassler [7]. We introduce the $SU(2)_U \times SU(2)_C \times SU(2)_T$ gauge interaction, which confines the preon superfields into the quark superfields in three generations. Each type of dynamics based on the $SU(2)_i$ ($i = U, C, T$) gauge interaction possesses the six doublet preon superfields, where the subscripts $i = U, C$ and T correspond to the first, second and third generation, respectively. The MSSM gauge group is embedded in the

$SU(6)$ global symmetry of the $SU(2)_i$ gauge dynamics.

The particle contents are as follows:

	$SU(2)_i$	$SU(5)_{SM}$	$U(1)_R$
P_i	2	5	1/4
N_i	2	1	3/4
$\bar{H}_i$	1	$\bar{5}$	1
$\bar{\Phi}_i$	1	$\bar{5}$	1/2

The superfield $\bar{H}_i$ is the down-type Higgs superfield, and $\bar{\Phi}_i$ is the matter superfield including the $SU(2)_L$ singlet quark of the down-type and the lepton doublet. In this paper, we use the $SU(5)$ GUT notation for simplicity. It is easy to decompose the notation into that for the MSSM gauge group. In the following discussion, we consider only the quark sector in the MSSM.

At high energy, where the $SU(2)_U \times SU(2)_C \times SU(2)_T$ gauge interaction becomes weak, most general tree-level superpotential is given by

$$W_{\text{tree}} = \bar{H}_U \sum_{i=U,C,T} \alpha_i [P_i N_i] + \bar{H}_C \sum_{i=C,T} \beta_i [P_i N_i] + \gamma \bar{H}_T [P_T N_T] , \quad (1)$$

where $[]$ denotes the contraction of $SU(2)_i$ indices by the ϵ -tensor, and α_i , β_i and γ are dimensionless coupling constants. We redefine the flavor index of $\bar{H}_i$ as above by the $SU(3)$ flavor rotation.

At low energy, where the gauge interaction becomes strong, the dynamical superpotential is generated as

$$W_{\text{dyn}} = \sum_{i=U,C,T} \frac{1}{\Lambda_i^3} \text{Pf}(V_i) , \quad (2)$$

where Λ_i is the dynamical scale of the $SU(2)_i$ gauge interaction, and V_i is a 6×6 antisymmetric tensor defined by

$$V_i = \begin{bmatrix} [P_i P_i] & [P_i N_i] \\ [N_i P_i] & 0 \end{bmatrix} \sim \Lambda_i \begin{bmatrix} \mathbf{10}_i & H_i \\ -H_i & 0 \end{bmatrix} . \quad (3)$$

The fields $\mathbf{10}_i$ and H_i are the effective fields as follows:

$$SU(5)_{SM}$$

$$\begin{aligned} \mathbf{10}_i &\sim [P_i P_i] / \Lambda_i & \mathbf{10} \\ H_i &\sim [P_i N_i] / \Lambda_i & \mathbf{5} \end{aligned} .$$

We can identify $\mathbf{10}_i$ and H_i with the superfield of the $\mathbf{10}$ representation and the up-type Higgs superfield of the $\mathbf{5}$ representation in the GUT framework, respectively. Then, we obtain the effective superpotential ¹

$$W_{\text{eff}} = \sum_{i=U,C,T} H_i \mathbf{10}_i \mathbf{10}_i + \sum_{i=U,C,T} \alpha_i \Lambda_i \bar{H}_U H_i + \sum_{i=C,T} \beta_i \Lambda_i \bar{H}_C H_i + \gamma \Lambda_T \bar{H}_T H_T . \quad (4)$$

Note that the first term is nothing but the Yukawa coupling, which is naturally $\mathcal{O}(1)$, and the other terms are the μ -terms of the Higgs superfields. By the strong $SU(2)_U \times SU(2)_C \times SU(2)_T$ dynamics, the large Yukawa couplings and the μ -terms are generated.

Let us assume that the pair of up- and down-type Higgs superfields $\bar{H}_T$ and H_T is the lightest of all the Higgs superfields. Then, integrating out the heavy superfields from Eq. (4), we obtain

$$W_{\text{eff}} = \alpha \frac{\Lambda_T}{\Lambda_U} H_T \mathbf{10}_U \mathbf{10}_U + \beta \frac{\Lambda_T}{\Lambda_C} H_T \mathbf{10}_C \mathbf{10}_C + H_T \mathbf{10}_T \mathbf{10}_T + \gamma \Lambda_T \bar{H}_T H_T , \quad (5)$$

where $\alpha = (\alpha_C \beta_T) / (\alpha_U \beta_C) - \alpha_T / \alpha_U$ and $\beta = -\beta_T / \beta_C$. For simplicity, we take $\alpha_i \sim \beta_j$. Then $\alpha \sim \beta \sim \mathcal{O}(1)$. If $\langle H_T \rangle \neq 0$ is realized, the masses of the up-type quarks are generated, and we can obtain the mass relation

$$m_u : m_c : m_t \sim \frac{\Lambda_T}{\Lambda_U} : \frac{\Lambda_T}{\Lambda_C} : 1 . \quad (6)$$

Therefore, the mass hierarchy among the up-type quarks originates from the hierarchy among the three composite scales, $\Lambda_T \ll \Lambda_C \ll \Lambda_U$. Note that if Λ_T is roughly the electroweak scale, we obtain the μ -term of the electroweak scale in Eq. (5).

¹ Since the first term in Eq. (4) can cause too rapid proton decay, we have to identify the $SU(2)_L$ singlet fields in $\mathbf{10}_i$ with new heavy fields to avoid this decay. The fields can have masses of order Λ_i , as considered by Nelson and Strassler. In the following discussion, we consider only the quark sector, as already mentioned.

III. THE DYNAMICAL SUSY BREAKING SECTOR

In order for the SUSY composite model introduced in the previous section to be realistic, SUSY should be broken. We construct the dynamical SUSY breaking sector in this section.

It is pointed out that the theory of the $SU(2)$ gauge interaction with four doublet and six singlet superfields can cause the dynamical SUSY breaking [6]. The dynamical SUSY breaking sector in our model has the extended structure of the theory. This sector is based on the $SU(2)_S \times SU(2)_M$ gauge group. To make our discussion clear, let us first consider only the $SU(2)_S$ dynamics. The particle contents are as follows:

	$SU(2)_S$	$SU(2)_U$	$SU(2)_C$	$U(1)_R$
Q_1	2	2	1	0
Q_2	2	1	2	0
Z	1	1	1	2
Z'	1	1	1	2
Z_5	1	1	1	2
Z_D	1	2	2	2
N	1	1	1	0

The gauge group $SU(2)_U \times SU(2)_C$ is embedded in the global $SU(4)$ flavor symmetry of the $SU(2)_S$ dynamics. It is known that this symmetry breaks down to the global $Sp(4)$ symmetry at low energy [3] if the $SU(2)_U \times SU(2)_C$ gauge interaction is switched off. Then, we require the tree-level superpotential to have the global $Sp(4)$ symmetry when the gauge interaction is ignored. We define Z , Z' and N as the singlet superfields, and Z_5 and Z_D as the **5** representation of this global symmetry.

Without loss of generality, tree-level superpotential is given by

$$\begin{aligned}
W_{\text{tree}} = & \lambda_Z Z ([Q_1 Q_1] + [Q_2 Q_2]) / 2 + \lambda_{Z'} Z' \{ ([Q_1 Q_1] + [Q_2 Q_2]) / 2 - \lambda_N N^2 \} \\
& + \lambda_5 \{ Z_5 ([Q_1 Q_1] - [Q_2 Q_2]) / 2 + Z_D [Q_1 Q_2] / 2 \} \quad , \quad (7)
\end{aligned}$$

where $[\]$ denotes the contraction of the $SU(2)_S$ indices. The representation of $[Q_i Q_j]$ ($i, j = 1, 2$) is decomposed into **1+5** representation of the $Sp(4)$ global symmetry, as above.

At low energy, where the $SU(2)_S$ gauge interaction becomes strong, the moduli space is dynamically deformed in order to satisfy the condition $\text{Pf}\hat{V} = \Lambda_S^4$, where $\hat{V}$ is 4×4 antisymmetric tensor given by

$$\hat{V} = \begin{bmatrix} [Q_1 Q_1] & [Q_1 Q_2] \\ [Q_2 Q_1] & [Q_2 Q_2] \end{bmatrix} \sim \Lambda_S \begin{bmatrix} V + V_5 & V_D \\ -V_D & V - V_5 \end{bmatrix}. \quad (8)$$

Here, Λ_S is the dynamical scale of the $SU(2)_S$ gauge interaction. The fields V , V_5 and V_D are the effective fields, as follows:

$$\begin{array}{ccc} & SU(2)_U & SU(2)_C \\ V + V_5 \sim [Q_1 Q_1] / \Lambda_S & \mathbf{1} & \mathbf{1} \\ V - V_5 \sim [Q_2 Q_2] / \Lambda_S & \mathbf{1} & \mathbf{1} \\ V_D \sim [Q_1 Q_2] / \Lambda_S & \mathbf{2} & \mathbf{2} \end{array} .$$

Since the condition $\text{Pf}\hat{V} = \Lambda_S^4$ contradicts the SUSY vacuum conditions required by the tree-level superpotential of Eq. (7), supersymmetry is dynamically broken [6].

To obtain the effective superpotential, we eliminate one of the effective fields with the condition $\text{Pf}\hat{V} = \Lambda_S^4$. Using the effective fields, the condition is described by

$$V^2 - V_5^2 - \frac{1}{2}V_D^2 = \Lambda_S^2. \quad (9)$$

Considering small fluctuations of V around $\langle V \rangle = \Lambda_S$, we obtain

$$V \sim \Lambda_S + \frac{1}{2\Lambda_S}V_5^2 + \frac{1}{4\Lambda_S}V_D^2. \quad (10)$$

Eliminating V from Eq. (7), the effective superpotential is given by

$$\begin{aligned} W_{\text{eff}} \sim & \lambda_Z Z \left(\Lambda_S^2 + \frac{1}{2}V_5^2 + \frac{1}{4}V_D^2 \right) + \lambda_{Z'Z'} \left(\Lambda_S^2 + \frac{1}{2}V_5^2 + \frac{1}{4}V_D^2 - \lambda_N N^2 \right) \\ & + \lambda_5 \Lambda_S \left(Z_5 V_5 + \frac{1}{2}Z_D V_D \right). \end{aligned} \quad (11)$$

This effective superpotential is one of the types of the O’Raifeartaigh model [10]. For small λ_Z compared with λ_5 , supersymmetry is broken by $\langle F_Z \rangle = \lambda_Z \Lambda_S^2$, where F_Z is the F -component of Z .

Note that the scalar potential derived from Eq. (11) has a ‘pseudo-flat’ direction; namely, the potential remains minimum along an arbitrary value of $\langle Z \rangle$ ². This pseudo-flat direction is lifted up by the quantum correction for the scalar potential of Z . If we consider the Yukawa coupling in Eq. (11), $\langle Z \rangle = 0$ is expected [11]. Then, the vacuum is realized at $\langle F_Z \rangle \neq 0$, $\langle \text{other } F\text{-components} \rangle = 0$, $\langle N \rangle = \Lambda_S / \sqrt{\lambda_N}$ and $\langle \text{other scalar components} \rangle = 0$. Note that there is no $U(1)_R$ symmetry breaking mass term of V_D in the effective superpotential, because $\langle Z \rangle = \langle Z' \rangle = 0$.

A strong $SU(2)_M$ gauge interaction is introduced to generate the mass term. We also introduce two doublet superfields, $\bar{Q}$ and Q , of the $SU(2)_M$ gauge group. In addition to the effective superpotential of Eq. (11), let us consider the new tree-level superpotential

$$W'_{\text{tree}} = \lambda_M N [\bar{Q}Q] \quad , \quad (12)$$

where $[\]$ denotes the contraction of the $SU(2)_M$ indices by the ϵ -tensor. The vacuum is realized with the same vacuum expectation values as discussed above and enforcing the condition $\langle \bar{Q} \rangle = \langle Q \rangle = 0$.

However, we should consider the non-perturbative effect of the strong $SU(2)_M$ gauge interaction at low energy. Then, the effective superpotential is given by

$$W'_{\text{eff}} = \lambda_M \Lambda_M N M + \frac{\Lambda_M^4}{M} \quad , \quad (13)$$

where Λ_M is the dynamical scale of the $SU(2)_M$ gauge interaction, and $M \sim [\bar{Q}Q] / \Lambda_M$ represents the effective fields. Now we obtain the total effective superpotential $\tilde{W}_{\text{eff}} = W_{\text{eff}} + W'_{\text{eff}}$ in the dynamical SUSY breaking sector.

² We use the same notation for both the superfield itself and the scalar component of the superfield.

We can see that $\langle Z' \rangle \neq 0$ is realized from the total superpotential. Indeed, from the two conditions $\partial \tilde{W}_{\text{eff}} / \partial M = 0$ and $\partial \tilde{W}_{\text{eff}} / \partial N = 0$, we obtain

$$\begin{aligned}\langle M \rangle &= \sqrt{\frac{1}{\lambda_M \langle N \rangle}} \Lambda_M^{3/2} = \frac{\lambda_N^{1/4} \Lambda_M^{3/2}}{\lambda_M^{1/2} \Lambda_S^{1/2}} , \\ \langle Z' \rangle &= \frac{\lambda_M}{2\lambda_{Z'} \lambda_N} \frac{\langle M \rangle}{\langle N \rangle} \Lambda_M = \frac{\lambda_M^{1/2}}{2\lambda_{Z'} \lambda_N^{1/4}} \frac{\Lambda_M^{5/2}}{\Lambda_S^{3/2}} .\end{aligned}\tag{14}$$

The $U(1)_R$ symmetry breaking mass term for the superfield V_D is generated.

IV. THE MEDIATION OF SUPERSYMMETRY BREAKING AND THE MASS SPECTRUM OF THE SUPERPARTNERS IN THE MSSM

In this section, we investigate the mediation of the supersymmetry breaking. This breaking is mediated to the preon sector and the MSSM sector by the $SU(2)_U \times SU(2)_C$ and $SU(5)_{SM}$ gauge interactions. Then, all of the superpartners in the MSSM obtain soft SUSY-breaking masses.

Let us extract the parts including V_D from the total effective superpotential $\tilde{W}_{\text{eff}}$ given in the previous section. These are given by

$$W_{\text{mess}} = \frac{1}{4}(\lambda_Z Z + \lambda_{Z'} Z') V_D^2 + \frac{1}{2} \lambda_5 \Lambda_S Z_D V_D .\tag{15}$$

Because $\langle F_Z \rangle \neq 0$ and $\langle Z' \rangle \neq 0$, the superfield V_D plays the role of the ‘messenger fields’ [4] to give soft SUSY-breaking masses to the $SU(2)_U \times SU(2)_C$ charged particles. In the following discussion, we assume $\lambda_Z \langle F_Z \rangle \ll (\lambda_{Z'} \langle Z' \rangle)^2$ and $\lambda_5 \Lambda_S \ll \lambda_{Z'} \langle Z' \rangle$, for simplicity.

Through the 1-loop radiative correction by the messenger fields V_D , the $SU(2)_U$ and $SU(2)_C$ gauginos obtain the soft SUSY-breaking masses

$$m_{\lambda_i} \sim \frac{\alpha_i}{4\pi} \frac{F}{m} ,\tag{16}$$

where $\alpha_i = g_i^2/4\pi$ is the coupling constant of the $SU(2)_i$ gauge interaction ($i = U, C$), $F = \lambda_Z \langle F_Z \rangle$ and $m = \lambda_{Z'} \langle Z' \rangle$.

The scalar preons, $\tilde{P}_i$ and $\tilde{N}_i$ ($i = U, C$), also obtain masses through the 2-loop radiative correction,

$$m_{\tilde{P}_i}^2 = m_{\tilde{N}_i}^2 \sim \frac{3}{2} \left(\frac{\alpha_i}{4\pi} \right)^2 \left(\frac{F}{m} \right)^2 . \quad (17)$$

The scalar preon masses are of the same order as the gaugino masses. Since the scalar preons have masses, the composite scalars, $\tilde{\mathbf{10}}_i$ and the up-type Higgs boson H_i , also have the soft SUSY-breaking masses. For simplicity, we assume that the masses of the composite scalars are twice as large as the corresponding scalar preon masses.

Furthermore, the gauginos in the MSSM obtain the soft SUSY-breaking masses through the radiative correction including the preon superfields P_i , since the preon superfield P_i has not only $SU(2)_i$ charge but also $SU(5)_{SM}$ charge. By the 3-loop diagram in Fig. 1 [5] [12], the masses are given by

$$m_{\lambda_N} \sim \frac{3\alpha_N}{8\pi} \frac{F}{m} \sum_{i=U,C} \left(\frac{\alpha_i}{4\pi} \right)^2 \ln \left(\frac{m}{\Lambda_i} \right) , \quad (18)$$

where α_N ($N = 1, 2, 3$) is the coupling constant of the $SU(N)$ gauge interaction in the standard model ³. Note that the preon superfields also play the role of the ‘messenger fields’.

Using the above results, we can estimate the mass spectrum in the MSSM. However, note that the results cannot be reliable at low energy, since the $SU(2)_i$ gauge interaction becomes strong there. For simplicity, we take $\alpha_H/4\pi = 1$ as a rough estimation. According to the above assumptions, we obtain

$$m_{\tilde{\mathbf{10}}_i} = m_{H_i} \sim 2m_{\tilde{P}_i} \sim \sqrt{6} \left(\frac{F}{m} \right) . \quad (19)$$

In the following discussion, we regard $\tilde{m} \equiv m_{\tilde{\mathbf{10}}_i}$ as a free parameter. Then, the MSSM gaugino masses are rewritten as

³ In this calculation, an infrared divergence occurs. This implies that the mass at zero momentum cannot be defined. We have taken Λ_i as the cutoff parameter of the infrared divergence, since the preon superfields P_i are confined at an energy lower than Λ_i .

$$m_{\lambda_N} \sim \frac{\sqrt{6}\alpha_N}{16\pi} \tilde{m} \sum_{i=U,C} \ln(m/\Lambda_i) \sim \frac{3\alpha_N}{2} \tilde{m} , \quad (20)$$

where we fix the value of the free parameter m such that $\sum_{i=U,C} \ln(m/\Lambda_i) = 4\sqrt{6}\pi$.

Since the MSSM gauginos and the scalar quarks in the first two generations have soft SUSY-breaking masses, the other scalar partners in the MSSM also obtain masses through radiative corrections by the gauginos and the scalars. The scalar partner of $\mathbf{10}_T$ obtains a mass mainly by the 1-loop correction due to the $SU(3)_c$ gaugino and the 2-loop corrections due to $\tilde{\mathbf{10}}_U$ and $\tilde{\mathbf{10}}_C$:

$$m_{\mathbf{10}_T}^2 \sim \frac{8\alpha_3}{3\pi} m_{\lambda_3}^2 \ln(\Lambda_T/m_{\lambda_3}) - \frac{2\alpha_3^2}{\pi^2} \tilde{m}^2 \ln(\Lambda_T/\tilde{m}) . \quad (21)$$

The Higgs bosons obtain masses mainly by the 1-loop correction due to the $SU(2)_L$ gaugino and the 2-loop corrections due to $\tilde{\mathbf{10}}_U$ and $\tilde{\mathbf{10}}_C$:

$$m_{\bar{H}_T}^2 \sim m_{H_T}^2 \sim \frac{3\alpha_2}{2\pi} m_{\lambda_2}^2 \ln(\Lambda_T/m_{\lambda_2}) - \frac{9\alpha_2^2}{8\pi^2} \tilde{m}^2 \ln(\Lambda_T/\tilde{m}) . \quad (22)$$

Note that, since the 2-loop corrections give negative contributions to the mass squared, our model potentially has a problem of $SU(3)_c$ color breaking [13]. However, we can avoid this problem by fixing the parameters such as $m \gg \Lambda_i$ (see Eq. (20)). The soft SUSY-breaking B -term, $B\bar{H}_T H_T + \text{h.c.}$, in the Higgs potential is induced mainly by the $SU(2)_L$ gaugino loop, and we obtain

$$B \sim \frac{3\alpha_2}{2\pi} m_{\lambda_2} \mu \ln(\Lambda_T/m_{\lambda_2}) , \quad (23)$$

where $\mu = \gamma\Lambda_T$.

Here, we list the masses of the superpartners to be used in the following discussion:

$$\begin{aligned} m_{\lambda_3} &\sim 1.8 \times 10^{-1} \tilde{m} , \\ m_{\lambda_2} &\sim 5.0 \times 10^{-2} \tilde{m} , \\ m_{\mathbf{10}_T} &\sim 7.8 \times 10^{-2} \tilde{m} , \\ m_{\bar{H}_T} &\sim m_{H_T} \sim 8.1 \times 10^{-3} \tilde{m} , \\ B &\sim 2.8 \times 10^{-3} \mu \tilde{m} . \end{aligned} \quad (24)$$

We have used $\alpha_3 \sim 0.12$ and $\alpha_2 \sim 0.033$ here, and we take $\Lambda_T/m_{\lambda_3} \sim 10$, for simplicity.

To obtain an experimentally acceptable mass spectrum in the MSSM [14], it is required that the scalar quarks in the first two generations be very heavy; namely, $\tilde{m} \geq \mathcal{O}(10 \text{ TeV})$. However, note that this value implies no contradiction with the naturalness criterion [1]. Since the Yukawa coupling constants of these quarks are very small, the contribution to the self-energy of the Higgs bosons remains less than the electroweak scale, even if $\tilde{m} \geq \mathcal{O}(10 \text{ TeV})$. On the other hand, the other superpartners have masses less than 1 TeV. Therefore, the mass spectrum in our model is one example of the ‘effective supersymmetry’ model proposed by Cohen, Kaplan and Nelson [9].

V. THE ELECTROWEAK SYMMETRY BREAKING

In order for our model to be realistic, the electroweak symmetry should be broken. In this section, we investigate whether the symmetry breaking is realized or not by using the mass spectrum obtained the previous section.

The Higgs potential is given by

$$V = (\mu^2 + m_{\bar{H}_T}^2)|\bar{H}_T|^2 + (\mu^2 + m_{H_T}^2)|H_T|^2 + (B\bar{H}_TH_T + \text{h.c.}) + \frac{1}{2} \left(\frac{M_Z}{v} \right)^2 (|\bar{H}_T|^2 - |H_T|^2)^2, \quad (25)$$

where $M_Z = 91 \text{ GeV}$ is the Z-boson mass, and $v = 246 \text{ GeV}$. Using the result from Eq. (24), we can obtain

$$(\mu^2 + m_{\bar{H}_T}^2)(\mu^2 + m_{H_T}^2) - B^2 > 0$$

for arbitrary values of μ and $\tilde{m}$. Therefore, the electroweak symmetry is not broken in this potential.

Then, we consider the radiative correction of the Higgs potential due to the large top Yukawa coupling. The 1-loop effective potential induced by the top and scalar top quarks is given by

$$V_{1\text{-loop}} = \frac{3}{8\pi^2} \int_0^{\Lambda_T^2} dk_E^2 k_E^2 \left[\ln \left(1 + \frac{g_t^2 |H_T|^2}{k_E^2 + m_{\mathbf{10}_T}^2} \right) - \ln \left(1 + \frac{g_t^2 |H_T|^2}{k_E^2} \right) \right] , \quad (26)$$

where we use Λ_T as a cutoff parameter because of the compositeness of the top quark superfield and the up-type Higgs boson. In Eq. (26), the first and second terms in the square brackets are given by the loop corrections of the scalar top and top quarks, respectively. One can check that $V_{1\text{-loop}} \rightarrow 0$ in the SUSY limit $m_{\mathbf{10}_T}^2 \rightarrow 0$. Now, we obtain the effective potential $V_{\text{eff}} = V + V_{1\text{-loop}}$ from Eq. (25) and (26).

In order for the electroweak symmetry to be broken, two minimization conditions, $\partial V_{\text{eff}}/\partial \bar{H}_T = 0$ and $\partial V_{\text{eff}}/\partial H_T = 0$, should be satisfied with nonzero values of $\langle \bar{H}_T \rangle$ and $\langle H_T \rangle$. In addition, these vacuum expectation values should satisfy the relation $\langle \bar{H}_T \rangle^2 + \langle H_T \rangle^2 = v^2/2$. Then, the minimization conditions are described by

$$\mu^2 + m_{\bar{H}_T}^2 + \frac{1}{2} M_Z^2 \cos 2\beta + B \tan \beta = 0 , \quad (27)$$

$$\begin{aligned} & \mu^2 + m_{H_T}^2 - \frac{1}{2} M_Z^2 \cos 2\beta + B \cot \beta \\ & + \frac{3}{4\pi^2} \frac{m_t^2}{v^2 \sin^2 \beta} \left[m_t^2 \ln \left(\frac{\Lambda_T^2 + m_t^2}{m_t^2} \right) - (m_{\mathbf{10}_T}^2 + m_t^2) \ln \left(\frac{\Lambda_T^2 + m_{\mathbf{10}_T}^2 + m_t^2}{m_{\mathbf{10}_T}^2 + m_t^2} \right) \right] = 0 , \end{aligned} \quad (28)$$

where we use the definitions $\langle \bar{H}_T \rangle = v \cos \beta / \sqrt{2}$, $\langle H_T \rangle = v \sin \beta / \sqrt{2}$ and $m_t^2 = g_t^2 \langle H_T \rangle^2$ for the top quark mass.

We will show that there is a realistic solution by substituting realistic values of the parameters into Eqs. (27) and (28). There are four independent unknown parameters, μ , $\tilde{m}$, $\tan \beta$ and Λ_T . When we fit the values of two of these parameters as $\mu = -210 \text{ GeV}$ and $\tilde{m} = 6 \text{ TeV}$, Eqs. (27) and (28) are regarded as equations to determine $\tan \beta$ and Λ_T , respectively. Then, we can find the solution ⁴

$$\tan \beta \sim 12 , \quad \Lambda_T \sim 11 \text{ TeV} ,$$

where we take $m_t = 175 \text{ GeV}$. The values of $|\tan \beta|$ and Λ_T become large (small) as $|\mu|$ ($\tilde{m}$) becomes large.

⁴ Our assumption $\Lambda_T/m_{\lambda_3} \sim 10$ is satisfied by this solution.

The input value $\tilde{m} = 6$ TeV gives an experimentally acceptable mass spectrum in the MSSM; for example, $m_{\lambda_3} \sim 1$ TeV from Eq. (24). From this solution, we can obtain the hierarchy $m_{\tilde{10}_T} \ll \tilde{m} \sim \Lambda_T \ll \Lambda_C \ll \Lambda_U$, which should be satisfied for the mechanism of Nelson and Strassler to work. This hierarchy also forbids the Higgs bosons (except for $\bar{H}_T$ and H_T) to obtain nonzero vacuum expectation values because of their very large μ -terms. On the other hand, the μ -term of $\bar{H}_T$ and H_T can become of the electroweak scale with a not so small parameter $\gamma \sim 10^{-2}$. As a result, the radiative-breaking scenario is realized with a realistic solution.

VI. THE MASSES OF THE DOWN-TYPE QUARKS

In the previous sections, the masses of the down-type quarks were not considered. In this section, we discuss the method to generate the masses of the down-type quarks.

Since the quark doublets are composed of two preons, we cannot introduce the Yukawa coupling of the down-type quarks with renormalizable terms in the superpotential. Following to Nelson and Strassler [7], let us introduce heavy fields $\bar{S}_i$ and S_i as follows:

	$SU(2)_i$	$U(1)_R$
$\bar{S}_i$	2	3/4
S_i	2	5/4

Here, $i = U, C$ and T correspond to each generation. For simplicity, we discuss only the third generation.

In addition to the tree-level superpotential of Eq. (1), we can introduce the superpotential

$$W = \lambda_{\bar{S}_T} \bar{H}_T [P_T \bar{S}_T] + \lambda_{S_T} [P_T S_T] \Phi_T - m_{\bar{s}s} \bar{S}_T S_T , \quad (29)$$

where $\lambda_{\bar{S}_T}$ and λ_{S_T} are dimensionless coupling constants, and $m_{\bar{s}s}$ is the mass parameter. Integrating out the heavy fields, we obtain

$$W = \frac{\lambda_{\bar{S}_T} \lambda_{S_T}}{m_{\bar{s}s}} \bar{H}_T [P_T P_T] \Phi_T . \quad (30)$$

Then, after the confinement of $[P_T P_T]$, this superpotential gives the Yukawa coupling of the bottom quark,

$$W = \lambda_{\bar{S}_T} \lambda_{S_T} \frac{\Lambda_T}{m_{\bar{s}s}} \bar{H}_T \Phi_T \mathbf{10}_T . \quad (31)$$

Note that the mass hierarchy between the top and bottom quarks is obtained by $\Lambda_T \ll m_{\bar{s}s}$. This mechanism was introduced by Nelson and Strassler.

However, we should explain the origin of the mass parameter $m_{\bar{s}s}$. In addition to the effective superpotential $\tilde{W}_{\text{eff}}$ in section III, let us introduce the superpotential

$$W = \lambda_{\bar{s}s} N [\bar{S}_T S_T] . \quad (32)$$

Note that the vacuum discussed in section III is not changed by this introduction. We can obtain the mass term of $\bar{S}_T$ and S_T by $\langle N \rangle = \Lambda_S / \sqrt{\lambda_N}$. The origin of the mass term is the dynamical scale of the $SU(2)_S$ gauge interaction. Therefore, the mass hierarchy between the top and bottom quarks originates from the hierarchy between the composite and the dynamical SUSY breaking scales.

It is easy to extend our discussion to the three generation case. However, our model has no mechanism to explain the mass hierarchy between the down-type quarks in the different generations. The explanation of the masses of the down-type quarks remains an open problem in our model.

VII. SUMMARY

We have constructed a composite model of quarks with ‘effective supersymmetry’. The model is based on the gauge group $(SU(2)_S \times SU(2)_M) \times (SU(2)_U \times SU(2)_C \times SU(2)_T) \times SU(5)_{SM}$.

In the dynamical SUSY breaking sector, supersymmetry is dynamically broken by the strong $SU(2)_S$ gauge dynamics. This dynamics also generates the $SU(2)_U \times SU(2)_C$ bi-doublet superfield V_D as a composite field. The $U(1)_R$ symmetry-breaking mass of V_D is

generated by the strong $SU(2)_M$ gauge dynamics. Then, the bi-doublet superfield plays the role of the messenger field to mediate the SUSY breaking to the preon sector in the first two generations.

In the preon sector, the preon superfields are confined in the up-type Higgs superfield H_i of the **5** representation and the superfield $\mathbf{10}_i$ of the **10** representation by the non-perturbative effect of the $SU(2)_i$ gauge interaction. A large top Yukawa coupling is dynamically generated. On the other hand, small Yukawa couplings of the up and charm quarks are effectively generated through the mixing of the up-type Higgs superfields. The mass hierarchy among the up-type quarks originates from the hierarchy among the three composite scales.

SUSY breaking is mediated to the preon sector and the MSSM sector through the radiative correction by the $SU(2)_U \times SU(2)_C$ bi-doublet superfield V_D and the preon superfield P_i ($i = U, C$). In particular, the MSSM gauginos obtain masses in a manner described by the 3-loop diagram in Fig. 1. Here, it is crucial for the preon superfield P_i to have charges both of the $SU(2)_i$ and the MSSM gauge groups, and it plays the role of the ‘messenger fields’. In order to obtain an experimentally acceptable mass spectrum in the MSSM, the scalar quarks in the first two generations need masses of order 10 TeV. On the other hand, the other superpartners need masses less than 1 TeV. Therefore, the mass spectrum in our model is an example of the ‘effective supersymmetry’ model of Cohen, Kaplan and Nelson.

In our model, the electroweak symmetry is broken by the radiative breaking scenario. The conditions to realize this scenario are satisfied with an experimentally acceptable mass spectrum in the MSSM. Our result is consistent with the condition for the mechanism of Nelson and Strassler to work. The μ -term of $\bar{H}_T$ and H_T becomes the electroweak scale without a very small parameter, because of the solution $\Lambda_T \sim 10$ TeV.

The masses of the down-type quarks are introduced by the higher dimensional terms as proposed by Nelson and Strassler. In our model, the origin of the mass term of $\bar{S}_T$ and S_T is the dynamical scale of the $SU(2)_S$ gauge interaction. Then, the mass hierarchy between the top and bottom quarks originates from the hierarchy between the composite and the

dynamical SUSY breaking scales. However, there is no mechanism to explain the hierarchy among the masses of the down-type quarks in different generations.

FIGURES

FIG. 1. The 3-loop diagram for the soft SUSY-breaking masses of the MSSM gauginos. The double solid and large-dotted lines denote the propagators of the fermion Ψ_{P_i} and scalar $\tilde{P}_i$ components of the preon superfield P_i , respectively. The solid and small-dotted line in the loop denote the propagators of the fermion and scalar components of V_D , respectively. The crosses denote the insertions of F and m . The propagators of the $SU(2)_U$ and $SU(2)_C$ gauginos are denoted by the vertical solid lines with the wavy curve.
